Part I
The Expand/Reduce Transformation

So I Was Asked...

• “So, you study about computers? What programs have you written?”

• I had to explain that my research is more about how to construct correct programs.

• Correctness: that a program does what it is supposed to do.

• “What do you mean? Doesn’t a program always does what it is told to do?”

1 Prelude

Maximum Segment Sum

• Given a list of numbers, find the maximum sum of a consecutive segment.

  - \([-1, 3, 3, -4, -1, 4, 2, -1]\) ⇒ 7
  - \([-1, 3, 1, -4, -1, 4, 2, -1]\) ⇒ 6
  - \([-1, 3, 1, -4, -1, 1, 2, -1]\) ⇒ 4

• Not trivial. However, there is a linear time algorithm.

  \[
  \begin{array}{cccccccc}
  -1 & 3 & 1 & -4 & -1 & 1 & 2 & -1 \\
  3 & 4 & 1 & 0 & 2 & 3 & 2 & 0 & 0 \quad (up + right) \uparrow 0 \\
  4 & 4 & 3 & 3 & 3 & 2 & 0 & 0 \quad up \uparrow right
  \end{array}
  \]

A Simple Program Whose Proof is Not

• The specification: \(\max \{ \text{sum} (i, j) \mid 0 \leq i \leq j \leq N \}\), where \(\text{sum} (i, j) = a[i] + a[i + 1] + \ldots + a[j]\).

• The program:

  ```c
  s = 0; m = 0;
  for (i=0; i<=N; i++) {
    s = max(0, a[j]+s);
    m = max(m, s);
  }
  ```

1
They do not look like each other at all!
– Moral: programs that appear “simple” might not be really that simple!

When we are given only the specification, can we construct the program?

**Verification v.s. Derivation**
How do we know a program is correct with respect to a specification?

• Verification: given a program, prove that it is correct with respect to some specification.
• Derivation: start from the specification, and attempt to construct only correct programs!

Theoretical development of one side benefits the other.

**Program Derivation**

• Wikipedia: *program derivation* is the derivation of a program from its specification, by mathematical means.
• To write a formal specification (which could be non-executable), and then apply mathematically correct rules in order to obtain an executable program.
• The program thus obtained is correct by construction.

**A Typical Derivation**

\[
\max \{ \text{sum} (i, j) | 0 \leq i \leq j \leq N \} \\
= \{ \text{Premise 1} \} \\
\max \cdot \text{map} \cdot \text{sum} \cdot \text{concat} \cdot \text{map inits} \cdot \text{tails} \\
= \{ \text{Premise 2} \} \\
\ldots \\
= \{ \ldots \} \\
\text{The final program!}
\]

**It’s How We Get There That Matters!**

\[
\text{Meaning of Life} \\
= \{ \text{Premise 1} \} \\
\ldots \\
= \{ \text{Premise 2} \} \\
\ldots \\
= \{ \ldots \} \\
42!
\]

The answer may be simple. It is how we get there that matters.
Functional Programming

- In program derivation, programs are entities we manipulate. Procedural programs (e.g. C programs), however, are difficult to manipulate because they lack nice properties.
- In C, we do not even have \( f(3) + f(3) = 2 \times f(3) \).
- In functional programming, programs are viewed as mathematical functions that can be reasoned algebraically, thus more suitable for program derivation.
- However, we will talk about procedural program derivation in the latter part of this course.

2 Preliminaries

2.1 Functions

Functions

- For the purpose of this lecture, it suffices to assume that functional programs actually denote functions from sets to sets.
  - The reality is more complicated. But that is out of the scope of this course.
- Functions can be viewed as sets of pairs, each specifies an input-output mapping.
  - E.g. the function \( \text{square} \) is specified by \( \{(1,1),(2,4),(3,9)\ldots\} \).
  - Function application is denoted by juxtaposition, e.g. \( \text{square} \, 3 \).
- Given \( f : \alpha \rightarrow \beta \) and \( g : \beta \rightarrow \gamma \), their composition \( g \cdot f :: \alpha \rightarrow \gamma \) is defined by \( (g \cdot f) \, a = g(f \, a) \).

Recursively Defined Functions

- Functions (or total functions) can be recursively defined:
  
  \[
  \begin{align*}
  \text{fact} \, 0 &= 1, \\
  \text{fact} \,(n+1) &= (n+1) \times \text{fact} \, n.
  \end{align*}
  \]

  As a simplified view, we take \( \text{fact} \) as the least set satisfying the equations above.
  - As a result, any total function satisfying the equations above is \( \text{fact} \). This is a long story cut short, however!
- Applying \( \text{fact} \) to a value:

  \[
  \begin{align*}
  \text{fact} \, 3 &= 3 \times \text{fact} \, 2 \\
  &= 3 \times 2 \times \text{fact} \, 1 \\
  &= 3 \times 2 \times \text{fact} \, 1 \\
  &= 3 \times 2 \times 1 \times 1.
  \end{align*}
  \]
2.2 Data Structures

Natural Numbers and Lists

- Natural numbers: \( data \ N = 0 \ | \ 1 + N \).
  - E.g. 3 can be seen as being composed out of \( 1 + (1 + 0) \).
- Lists: \( data \ [a] = [[]] \ | \ a : [a] \).
  - A list with three items 1, 2, and 3 is constructed by \( 1 : (2 : (3 : [[]])) \), abbreviated as \( [1, 2, 3] \).
  - \( hd \ (x : xs) = x \).
  - \( tl \ (x : xs) = xs \).
- Noticed some similarities?

Binary Trees

For this course, we will use two kinds of binary trees: internally labelled trees, and externally labelled ones:

- \( data \ iTree \ \alpha = Null \ | \ Node \ \alpha \ (iTree \ \alpha) \ (iTree \ \alpha) \).
  - E.g. \( Node 3 \ (Node 2 Null Null) \ (Node 1 Null \ (Node 4 Null Null)) \).
- \( data \ eTree \ \alpha = Tip \ \alpha \ | \ Bin \ (eTree \ \alpha) \ (eTree \ \alpha) \).
  - E.g. \( Bin \ (Bin \ (Tip 1) \ (Tip 2)) \ (Tip 3) \).

3 The Expand/Reduce Transformation

Sum and Map

- The function \( sum \) adds up the numbers in a list:
  \[
  \begin{align*}
  sum & :: [Int] \to Int \\
  sum [] & = 0 \\
  sum (x : xs) & = x + sum xs.
  \end{align*}
  \]
  - E.g. \( sum [7, 9, 11] = 27 \).
- The function \( map f \) takes a list and builds a new list by applying \( f \) to every item in the input:
  \[
  \begin{align*}
  map & :: (\alpha \to \beta) \to [\alpha] \to [\beta] \\
  map f [] & = [] \\
  map f (x : xs) & = f x : map f xs.
  \end{align*}
  \]
  - E.g. \( map \ square [3, 4, 6] = [9, 16, 36] \).
3.1 Example: Sum of Squares

Sum of Squares

- Given a sequence $a_1, a_2, \ldots, a_n$, compute $a_1^2 + a_2^2 + \ldots + a_n^2$. Specification: $\text{sumsq} = \text{sum} \cdot \text{map} \ \text{square}$.
- The spec. builds an intermediate list. Can we eliminate it?
- The input is either empty or not. When it is empty:

\[
\begin{align*}
\text{sumsq} & [] \\
         & = \{ \text{definition of sumsq} \} \\
         & (\text{sum} \cdot \text{map} \ \text{square}) [] \\
         & = \{ \text{function composition} \} \\
         & \text{sum} \ (\text{map} \ \text{square} []) \\
         & = \{ \text{definition of map} \} \\
         & \text{sum} [] \\
         & = \{ \text{definition of sum} \} \\
         & 0.
\end{align*}
\]

Sum of Squares, the Inductive Case

- Consider the case when the input is not empty:

\[
\begin{align*}
\text{sumsq} (x : xs) \\
         & = \{ \text{definition of sumsq} \} \\
         & \text{sum} \ (\text{map} \ \text{square} (x : xs)) \\
         & = \{ \text{definition of map} \} \\
         & \text{sum} \ (\text{square} \ x : \text{map} \ \text{square} \ xs) \\
         & = \{ \text{definition of sum} \} \\
         & \text{square} \ x + \text{sum} \ (\text{map} \ \text{square} \ xs) \\
         & = \{ \text{definition of sumsq} \} \\
         & \text{square} \ x + \text{sumsq} \ xs.
\end{align*}
\]

We have therefore constructed a recursive definition of $\text{sumsq}$:

\[
\begin{align*}
\text{sumsq} [] & = 0 \\
\text{sumsq} (x : xs) & = \text{square} \ x + \text{sumsq} \ xs.
\end{align*}
\]

Unfold/Fold Transformation

- Perhaps the most intuitive, yet still handy, style of functional program derivation.
- Keep unfolding the definition of functions, apply necessary rules, and finally fold the definition back.
- It works under the assumption that a function satisfying the derived equations is the function defined by the equations.
- In this course, we use the terms “fold” and “unfold” for another purpose. Therefore we refer to this technique as the expand/reduce transformation.
3.2 Proof by Induction

Proving Auxiliary Properties

• Our style of program derivation:

\[ expression = \{ \text{some property} \} \]

... .

• Some of the properties are rather obvious. Some needs to be proved separately.

• In this section we will practice perhaps the most fundamental proof technique, which is still very useful.

The Induction Principle

• Recall the so called “mathematical induction”. To prove that a property \( p \) holds for all natural numbers, we need to show:
  – that \( p \) holds for 0, and
  – if \( p \) holds for \( n \), it holds for \( n + 1 \) as well.

• We can do so because the set of natural numbers is an inductive type.

• The type of finite lists is an inductive types too. Therefore the property \( p \) holds for all finite lists if
  – property \( p \) holds for \([\]\), and
  – if \( p \) holds for \( xs \), it holds for \( x: xs \) as well.

Appending Two Lists

• The function (++) appends two lists into one:

\[
(++) :: [a] \rightarrow [a] \rightarrow [a] \\
[\] ++ ys = ys \\
(x : xs) ++ ys = x : (xs ++ ys).
\]

• E.g.

\[
[1,2] \; ++ \; [3,4] \\
= \; 1 : ([2] \; ++ \; [3,4]) \\
= \; 1 : (2 : ([] \; ++ \; [3,4])) \\
= \; 1 : (2 : [3,4]) \\
= \; [1,2,3,4].
\]

• The time it takes to compute \( xs ++ ys \) is proportional to the length of \( x \).
Sum Distributes into Append
Example: let us show that \( \text{sum} \ (\text{xs} \ + \ + \ \text{ys}) = \text{sum} \ \text{xs} + \text{sum} \ \text{ys} \), for finite lists \( \text{xs} \) and \( \text{ys} \).

Case \([\ ]\):
\[
\text{sum} \ ([\ ] + \ + \ \text{ys}) \\
= \quad \{ \text{definition of } \text{sum} \} \\
0 + \text{sum} \ \text{ys} \\
= \quad \{ \text{arithmetic} \} \\
\text{sum} \ \text{ys} \\
= \quad \{ \text{by definition of } (+ +), \ [\ ] + + \ \text{ys} = \ \text{ys} \} \\
\text{sum} \ ([\ ] + + \ \text{ys}).
\]

Sum Distributes into Append, the Inductive Case
Case \(x: \text{xs}\):
\[
\text{sum} \ ((x: \text{xs}) + + \ \text{ys}) \\
= \quad \{ \text{definition of } \text{sum} \} \\
(x + \text{sum} \ \text{xs}) + + \ \text{ys} \\
= \quad \{ (+) \text{ is associative: } (a + b) + c = a + (b + c) \} \\
x + (\text{sum} \ \text{xs} + \text{sum} \ \text{ys}) \\
= \quad \{ \text{induction hypothesis} \} \\
x + \text{sum} \ ((\text{xs} + + \ \text{ys}) \\
= \quad \{ \text{definition of } \text{sum} \} \\
\text{sum}(x: (\text{xs} + + \ \text{ys})) \\
= \quad \{ \text{definition of } (+ +) \} \\
\text{sum}(x: (\text{xs}) + + \ \text{ys}).
\]

Some Properties to be Proved
The following properties are left as exercises for you to prove. We will make use of some of them in the lecture.

- Concatenation is associative:
  \[(xs + + ys) + + zs = xs + + (ys + + zs)\].
  (Note that the right-hand side is in general faster than the left-hand side.)

- The function \texttt{concat} concatenates a list of lists:
  \[
  \texttt{concat} \ [\ ] = [\], \quad \texttt{concat} \ (x : xss) = xs + + \texttt{concat} \ xss.
  \]
  E.g. \texttt{concat} [[1,2], [3,4], [5]] = [1,2,3,4,5]. We have \texttt{sum} \cdot \texttt{concat} = \texttt{sum} \cdot \texttt{map} \ \texttt{sum}. 

Inductive Proofs on Trees
Recall the datatype:

\[
data \text{iTree} \alpha = \text{Null} | \text{Node} \alpha (\text{iTree} \alpha) (\text{iTree} \alpha).
\]

What is the induction principle for \text{iTree}? A property \( p \) holds for all finite \text{iTrees} if . . .

- the property \( p \) holds for \text{Null}, and
- for all \( a,t,u \), if \( p \) holds for \( t \) and \( u \), then \( p \) holds for \text{Node} \( a \) \( t \) \( u \).

3.3 Accumulating Parameter

Example: Reversing a List

- The function \text{reverse} is defined by:

\[
\begin{align*}
\text{reverse} [ ] &= [], \\
\text{reverse} (x:xs) &= \text{reverse} xs ++ [x].
\end{align*}
\]

E.g. \text{reverse} \([1,2,3,4]\) = ((([] ++ [4]) ++ [3]) ++ [2]) ++ [1] = [4,3,2,1].

- But how about its time complexity? Since \((++\) is \(O(n)\), it takes \(O(n^2)\) time to revert a list this way.

- Can we make it faster?

Introducing an Accumulating Parameter

- Let us consider a generalisation of \text{reverse}. Define:

\[
\text{rcat} \hspace{1mm} xs \hspace{1mm} ys = \text{reverse} \hspace{1mm} xs \hspace{1mm} ++ \hspace{1mm} ys.
\]

- If we can construct a fast implementation of \text{rcat}, we can implement \text{reverse} by:

\[
\text{reverse} \hspace{1mm} xs = \text{rcat} \hspace{1mm} xs \hspace{1mm} [].
\]

Reversing a List, Base Case

Let us use our old trick of Expand/Reduce transformation. Consider the case when \( xs \) is \([],):

\[
\begin{align*}
\text{rcat} \hspace{1mm} [ ] \hspace{1mm} ys &= \{ \text{definition of} \hspace{1mm} \text{rcat} \} \\
\text{reverse} \hspace{1mm} [ ] \hspace{1mm} ++ \hspace{1mm} ys &= \{ \text{definition of} \hspace{1mm} \text{reverse} \} \\
[ ] \hspace{1mm} ++ \hspace{1mm} ys &= \{ \text{definition of} \hspace{1mm} (++) \} \\
y.
\end{align*}
\]
Reversing a List, Inductive Case

Case $x : xs$:

\[
\begin{align*}
rcat (x : xs) ys &= \{ \text{definition of } rcat \} \\
reverse (x : xs) ++ ys &= \{ \text{definition of } reverse \} \\
(reverse \ xs ++ [x]) ++ ys &= \{ \text{since } (xs ++ ys) ++ zs = xs ++ (ys ++ zs) \} \\
reverse \ xs ++ ([x] ++ ys) &= \{ \text{definition of } rcat \} \\
rcat \ xs (x : ys).
\end{align*}
\]

Linear-Time List Reversal

- We have therefore constructed an implementation of $rcat$:

\[
\begin{align*}
rcat [] ys &= ys \\
rcat (x : xs) ys &= rcat \ xs (x : ys),
\end{align*}
\]

which runs in linear time!

- A generalisation of $reverse$ is easier to implement than $reverse$ itself? How come?

- If you try to understand $rcat$ operationally, it is not difficult to see how it works.
  - The partially reverted list is accumulated in $ys$.
  - The initial value of $ys$ is set by $reverse \ xs = rcat \ xs []$.
  - Hmm... it is like a loop, isn’t it?

Tracing Reverse

\[
\begin{align*}
reverse [1, 2, 3, 4] &= rcat [1, 2, 3, 4][] \\
&= rcat [2, 3, 4] [1] \\
&= rcat [3, 4] [2, 1] \\
&= rcat [4] [3, 2, 1] \\
&= rcat [] [4, 3, 2, 1] \\
&= [4, 3, 2, 1]
\end{align*}
\]

\[
\begin{align*}
reverse \ xs &= rcat \ xs [] \\
rcat [] ys &= ys \\
rcat (x : xs) ys &= rcat \ xs (x : ys)
\end{align*}
\]

\[
\begin{align*}
xs, ys &\leftarrow XS,[], \\
\text{while } xs \neq [] \text{ do} \\
&\hspace{1em} xs, ys \leftarrow tl \ xs, hd \ xs : ys; \\
\text{return } ys;
\end{align*}
\]
Tail Recursion

- Tail recursion: a special case of recursion in which the last operation is the recursive call.

\[
f x_1 \ldots x_n = \{\text{base case}\}
f x_1 \ldots x_n = f x'_1 \ldots x'_n
\]

- To implement general recursion, we need to keep a stack of return addresses. For tail recursion, we do not need such a stack.
- Tail recursive definitions are like loops. Each \( x_i \) is updated to \( x'_i \) in the next iteration of the loop.
- The first call to \( f \) sets up the initial values of each \( x_i \).

Accumulating Parameters

- To efficiently perform a computation (e.g. \( \text{reverse } xs \)), we introduce a generalisation with an extra parameter, e.g.:

\[
\text{rcat } xs\ ys = \text{reverse } xs ++ ys.
\]

- Try to derive an efficient implementation of the generalised function. The extra parameter is usually used to “accumulate” some results, hence the name.
  - To make the accumulation work, we usually need some kind of associativity.
- A technique useful for, but not limited to, constructing tail-recursive definition of functions.

Loop Invariants

To implement \( \text{reverse} \), we introduce \( \text{rcat} \) such that:

\[
\text{rcat } xs\ ys = \text{reverse } xs ++ ys.
\] (1)

**Functional:** We initialise \( \text{rcat} \) by:

\[
\text{reverse } xs = \text{rcat } xs\ [].
\]

and try to derive a faster version of \( \text{rcat} \) satisfying (1).

\[
\text{rcat } []\ ys = ys
\]
\[
\text{rcat } (x : xs)\ ys = \text{rcat } xs\ (y : ys)
\]

**Procedural:** We initialise the loop, and try to derive a loop body maintaining a loop invariant related to (1).

\[
xs, ys \leftarrow X:\ [];
\{\text{reverse } X = \text{reverse } xs ++ ys\}
\text{while } xs \neq []\ do
\quad xs, ys \leftarrow tl\ xs, \text{hd } xs : ys;
\text{return } ys;
\]
Accumulating Parameter: Another Example

- Recall the “sum of squares” problem:

\[
\begin{align*}
\text{sumsq} [] &= 0 \\
\text{sumsq} (x : xs) &= \text{square} \, x + \text{sumsq} \, xs.
\end{align*}
\]

The program still takes linear space (for the stack of return addresses). Let us construct a tail recursive auxiliary function.

- Introduce \(ssp \, xs \, n = \text{sumsq} \, xs + n\).

- Initialisation: \(\text{sumsq} \, xs = ssp \, xs \, 0\).

- Construct \(ssp\):

\[
\begin{align*}
ssp [] \, n &= 0 + n = n \\
ssp (x : xs) \, n &= (\text{square} \, x + \text{sumsq} \, xs) + n \\
&= \text{sumsq} \, xs + (\text{square} \, x + n) \\
&= ssp \, xs \, (\text{square} \, x + n).
\end{align*}
\]

3.4 Tupling

Steep Lists

- A steep list is a list in which every element is larger than the sum of those to its right:

\[
\begin{align*}
\text{steep} [] &= \text{true} \\
\text{steep} (x : xs) &= \text{steep} \, xs \land x > \text{sum} \, xs.
\end{align*}
\]

- The definition above, if executed directly, is an \(O(n^2)\) program. Can we do better?

- Just now we learned to construct a generalised function which takes more input. This time, we try the dual technique: to construct a function returning more results.

Generalise by Returning More

- Recall that \(\text{fst} (a, b) = a\) and \(\text{snd} (a, b) = b\).

- It is hard to quickly compute steep alone. But if we define

\[
\text{steepsum} \, xs = (\text{steep} \, xs, \text{sum} \, xs),
\]

and manage to synthesise a quick definition of steepsum, we can implement steep by steep = \(\text{fst} \cdot \text{steepsum}\).

- We again proceed by case analysis. Trivially,

\[
\text{steepsum} [] = (\text{true}, 0).
\]
Deriving for the Non-Empty Case

For the case for non-empty inputs:

\[
\text{steepsum}(x:xs) = \begin{cases} \text{definition of steepsum} \\ (\text{steep}(x:xs), \text{sum}(x:xs)) \end{cases} = \begin{cases} \text{definitions of steep and sum} \\ \text{extracting sub-expressions involving xs} \end{cases} = \begin{cases} \text{steep xs} \land x > \text{sum xs}, x + \text{sum xs} \end{cases} \]

\[
\text{let } (b, y) = (\text{steep xs}, \text{sum xs}) \\
\text{in } (b \land x > y, x + y) = \begin{cases} \text{definition of steepsum} \\ \text{let } (b, y) = \text{steepsum xs} \\
\text{in } (b \land x > y, x + y).\end{cases}
\]

Synthesised Program

- We have thus come up with:

\[
\begin{align*}
\text{steep} &= \text{fst} \cdot \text{steepsum} \\
\text{steepsum \[\]} &= (\text{true,0}) \\
\text{steepsum \(x:xs\)} &= \text{let } (b, y) = \text{steepsum xs} \\
&\quad \text{in } (b \land x > y, x + y),
\end{align*}
\]

which runs in \(O(n)\) time.

- Again we observe the phenomena that a more general function is easier to implement.

- It is actually common in inductive proofs, too. To prove a theorem, we sometimes have to generalise it so that we have a stronger inductive hypothesis.

- Talking about inductive proofs again, in the next lecture let us see a general pattern for induction.

Summary for the First Day

- Program derivation: constructing programs from their specifications, through formal reasoning.

- Expand/reduce transformation: the most fundamental kind of program derivation — expand the definitions of functions, and reduce them back when necessary.

- Most of the properties we need during the reasoning, for this course, can be proved by induction.

- Accumulating parameters: sometimes a more general program is easier to construct.
  
  - Sometimes used to construct loops. Closely related to loop invariants in procedural program derivation.
  
  - Usually relies on some associativity property to work.

- Tupling: a dual technique often used to generalise a function so that we can derive a quicker recursive definition.

- Like it so far? More fun tomorrow!
Part II

Fold, Unfold, and Hylomorphism

From Yesterday...

- Expand/reduce transformation: the most basic kind of program derivation. Expand the definitions of functions, and reduce them back when necessary.
- Proof by induction.
- Accumulating parameter: a handy technique for, among other purposes, deriving tail recursive functions.
- Tupling: a dual technique often used to generalise a function so that we can derive a quicker recursive definition.
- Today we will be dealing with slightly abstract concepts.

4 Folds

A Common Pattern We’ve Seen Many Times...

- \( \text{sum}[] = 0 \)
  \( \text{sum}(x:xs) = x + \text{sum}\,xs \)
- \( \text{length}[] = 0 \)
  \( \text{length}(x:xs) = 1 + \text{length}\,xs \)
- \( \text{map}\,f[] = [] \)
  \( \text{map}\,f(x:xs) = f\,x:\text{map}\,f\,xs \)
- This pattern is extracted and called \( \text{foldr} \):
  \[ \text{foldr}\,f\,e[] = e, \]
  \[ \text{foldr}\,f\,e(x:xs) = f\,x(\text{foldr}\,f\,e\,xs). \]

Replacing Constructors

- \( \text{foldr}\,f\,e[] = e \)
  \( \text{foldr}\,f\,e(x:xs) = f\,x(\text{foldr}\,f\,e\,xs) \)
- One way to look at \( \text{foldr}(\oplus)e \) is that it replaces \([\,]\) with \(e\) and \(\,;\,\) with \((\oplus)\):
  \[ \text{foldr}(\oplus)e[1,2,3,4] = \text{foldr}(\oplus)e(1:(2:(3:(4:[])))) \]
  \[ = 1 \oplus (2 \oplus (3 \oplus (4 \oplus e))). \]
- \( \text{sum} = \text{foldr}(+)0. \)
- \( \text{length} = \text{foldr}(\lambda x\,n.1+n)0. \)
- \( \text{map}\,f = \text{foldr}(\lambda x\,xs.f\,x:xs)[] . \)
- One can see that \( id = \text{foldr}(:)[] . \)
Some Trivial Folds on Lists

- Function `max` returns the maximum element in a list:
  - \( \text{max}[]} = -\infty \),
  - \( \text{max}(x : xs) = x \uparrow \text{max}xs \).
  - \( \text{max} = \text{foldr}(\uparrow)\cdot -\infty \).
- Function `prod` returns the product of a list:
  - \( \text{prod[]} = 1 \),
  - \( \text{prod}(x : xs) = x \times \text{prod}xs \).
  - \( \text{prod} = \text{foldr}(\times)1 \).
- Function `and` returns the conjunction of a list:
  - \( \text{and[]} = \text{true} \),
  - \( \text{and}(x : xs) = x \land \text{and}xs \).
  - \( \text{and} = \text{foldr}(\land)\cdot \text{true} \).
- Let’s emphasise again that `id` on lists is a fold:
  - \( \text{id[]} = [], \)
  - \( \text{id}(x : xs) = x : \text{id}xs \).
  - \( \text{id} = \text{foldr}(:)[] \).

4.1 The Fold-Fusion Theorem

Why Folds?

- The same reason we kept talking about patterns in design.
- Control abstraction, procedure abstraction, data abstraction,... can programming patterns be abstracted too?
- Program structure becomes an entity we can talk about, reason about, and reuse.
  - We can describe algorithms in terms of fold, unfold, and other recognised patterns.
  - We can prove properties about folds,
  - and apply the proved theorems to all programs that are folds, either for compiler optimisation, or for mathematical reasoning.
- Among the theorems about folds, the most important is probably the fold-fusion theorem.

The Fold-Fusion Theorem

The theorem is about when the composition of a function and a fold can be expressed as a fold.

**Theorem 1** (Fold-Fusion). Given \( f : \alpha \rightarrow \beta \rightarrow \beta, e : \beta, h : \beta \rightarrow \gamma, \) and \( g : \alpha \rightarrow \gamma \rightarrow \gamma \), we have:

\[
h \cdot \text{foldr} f e = \text{foldr} g(h e),
\]

if \( h(f x y) = g x(h y) \) for all \( x \) and \( y \).

For program derivation, we are usually given \( h, f, \) and \( e \), from which we have to construct \( g \).
Tracing an Example

Let us try to get an intuitive understand of the theorem:

\[
\begin{align*}
    h(foldr \ f \ e[a, b, c]) &= \{ \text{definition of foldr} \} \\
    &= h(f \ a(f \ b(f \ c \ e))) \\
    &= \{ \text{since } h(f \ x \ y) = g \ x \ (h \ y) \} \\
    &= g \ a(h(f \ b(f \ c \ e))) \\
    &= \{ \text{since } h(f \ x \ y) = g \ x \ (h \ y) \} \\
    &= g \ a(g \ b(h(f \ c \ e))) \\
    &= \{ \text{definition of foldr} \} \\
    &= foldr \ g \ (h \ e)[a, b, c].
\end{align*}
\]

Sum of Squares, Again

- Consider \( sum \cdot map \ square \) again. This time we use the fact that \( map \ f = foldr \ (mf \ f)[] \), where \( mf \ f \ xs = f \ x : xs \).

- \( sum \cdot map \ square \) is a fold, if we can find a \( ssq \) such that \( sum \ (mf \ square \ xs) = ssq \ x \ (sum \ xs) \). Let us try:

\[
\begin{align*}
    sum \ (mf \ square \ xs) &= \{ \text{definition of mf} \} \\
    &= sum \ (square \ x : xs) \\
    &= \{ \text{definition of sum} \} \\
    &= square \ x + sum \ xs \\
    &= \{ \text{let } ssq \ x \ y = square \ x + y \} \\
    &= ssq \ x \ (sum \ xs).
\end{align*}
\]

Therefore, \( sum \cdot map \ square = foldr \ ssq \ 0 \).

More on Folds and Fold-fusion

- Compare the proof with the one yesterday. They are essentially the same proof.

- Fold-fusion theorem abstracts away the common parts in this kind of inductive proofs, so that we need to supply only the “important” parts.

- Tupling can be seen as a kind of fold-fusion. The derivation of \( steepsum \), for example, can be seen as fusing:

\[
steepsum \cdot id = steepsum \cdot foldr(\:)[].
\]

- Not every function can be expressed as a fold. For example, \( tl \) is not a fold!
4.2 More Useful Functions Defined as Folds

Longest Prefix

- The function call \textit{takeWhile} \( p \) \( xs \) returns the longest prefix of \( xs \) that satisfies \( p \):

\[
\text{takeWhile} \ p \ [] = [], \quad \text{takeWhile} \ p \ (x : xs) = \begin{cases} x : \text{takeWhile} \ p \ xs & \text{if} \ p \ x \\ [] & \text{else} \end{cases}.
\]

- E.g. \( \text{takeWhile} \ (\leq 3) \) \( [1, 2, 3, 4, 5] \) = \( [1, 2, 3] \).

- It can be defined by a fold:

\[
\text{takeWhile} \ p = \text{foldr} \ (\text{take} \ p) \ [] , \quad \text{take} \ p \ x \ xs = \begin{cases} x : \text{take} \ p \ xs & \text{if} \ p \ x \\ [] & \text{else} \end{cases}.
\]

- Its dual, \( \text{dropWhile} \ (\leq 3) \) \( [1, 2, 3, 4, 5] \) = \( [4, 5] \), is not a fold.

All Prefixes

- The function \textit{inits} returns the list of all prefixes of the input list:

\[
inits \ [] = [[]], \quad \text{inits} \ (x : xs) = [] : \text{map} \ (x :) \ (\text{inits} \ xs).
\]

- E.g. \( \text{inits} \ [1, 2, 3] \) = \( [[]], [1], [1, 2], [1, 2, 3] \).

- It can be defined by a fold:

\[
inits = \text{foldr} \ \text{ini} \ [] , \quad \text{ini} \ x \ xss = [] : \text{map} \ (x :) \ xss.
\]

All Suffixes

- The function \textit{tails} returns the list of all suffixes of the input list:

\[
tails \ [] = [], \quad \text{tails} \ (x : xs) = \begin{cases} \text{let} \ (ys : yss) = \text{tails} \ xs \\ \text{in} \ (x : ys) : ys : yss \end{cases}.
\]

- E.g. \( \text{tails} \ [1, 2, 3] \) = \( [[1, 2, 3], [2, 3], [3], []] \).

- It can be defined by a fold:

\[
tails = \text{foldr} \ \text{til} \ [] , \quad \text{til} \ x \ (ys : yss) = (x : ys) : ys : yss.
\]
Scan

- \(\text{scanr } f\ e = \text{map } (\text{foldr } f\ e) \cdot \text{tails}\).
- E.g.
  \[
  \text{scanr } (+) 0 [1, 2, 3] \\
  = \text{map } \text{sum } (\text{tails } [1, 2, 3]) \\
  = \text{map } \text{sum } [[1, 2, 3], [2, 3], [3], []] \\
  = [6, 5, 3, 0].
  \]
- Of course, it is slow to actually perform \(\text{map } (\text{foldr } f\ e)\) separately. By fold-fusion, we get a faster implementation:
  \[
  \text{scanr } f\ e = \text{foldr } (\text{sc } f) [e],
  \]
  \[
  \text{sc } f\ x\ (y : y') = f\ x\ y : y' : y'.
  \]

4.3 Finally, Solving Maximum Segment Sum

Specifying Maximum Segment Sum

- Finally we have introduced enough concepts to tackle the maximum segment sum problem!
- A segment can be seen as a prefix of a suffix.
- The function \(\text{segs}\) computes the list of all the segments.
  \[
  \text{segs} = \text{concat } \cdot \text{map } \text{inits } \cdot \text{tails}.
  \]
- Therefore, \(\text{mss}\) is specified by:
  \[
  \text{mss} = \text{max } \cdot \text{map } \text{sum } \cdot \text{segs}.
  \]

The Derivation!

We reason:

\[
\begin{align*}
\text{mss} & = \text{max } \cdot \text{map } \text{sum } \cdot \text{concat } \cdot \text{map } \text{inits } \cdot \text{tails} \\
& = \{ \text{since } \text{map } f \cdot \text{concat } = \text{concat } \cdot \text{map } (\text{map } f) \} \\
& \quad \cdot \text{map } \text{max } \cdot \text{map } (\text{map } \text{sum}) \cdot \text{map } \text{inits } \cdot \text{tails} \\
& = \{ \text{since } \text{max } \cdot \text{concat } = \text{max } \cdot \text{map } \text{max} \} \\
& \quad \cdot \text{map } \text{max } \cdot \text{map } (\text{map } \text{sum}) \cdot \text{map } \text{inits } \cdot \text{tails} \\
& = \{ \text{since } \text{map } f \cdot \text{map } g = \text{map } (f \cdot g) \} \\
& \quad \cdot \text{map } (\text{max } \cdot \text{map } (\text{map } \text{sum}) \cdot \text{inits}) \cdot \text{tails}.
\end{align*}
\]
Recall the definition \(\text{scanr } f\ e = \text{map } (\text{foldr } f\ e) \cdot \text{tails}\). If we can transform \(\text{max } \cdot \text{map } \text{sum } \cdot \text{inits}\) into a fold, we can turn the algorithm into a scan, which has a faster implementation.
Maximum Prefix Sum

Concentrate on \( \max \cdot \text{map sum} \cdot \text{inits} \):

\[
\begin{align*}
\max \cdot \text{map sum} \cdot \text{inits} &= \{ \text{definition of init, init } x \ xss = [] : \text{map} \ (x : ) \ xss \} \\
\max \cdot \text{map sum} \cdot \text{foldr ini} [[]] &= \{ \text{fold fusion, see below} \} \\
\max \cdot \text{foldr zplus} [0].
\end{align*}
\]

The fold fusion works because:

\[
\begin{align*}
\text{map sum} \ (\text{init } x \ xss) &= \text{map sum} ([]) : \text{map} \ (x : ) \ xss \\
&= 0 : \text{map} \ (\text{sum} \ (x : )) \ xss \\
&= 0 : \text{map} \ (x+) (\text{map sum} \ xss).
\end{align*}
\]

Define \( zplus \ x \ xss = 0 : \text{map} \ (x+) \ xss \).

Maximum Prefix Sum, 2nd Fold Fusion

Concentrate on \( \max \cdot \text{map sum} \cdot \text{inits} \):

\[
\begin{align*}
\max \cdot \text{map sum} \cdot \text{inits} &= \{ \text{definition of init, init } x \ xss = [] : \text{map} \ (x : ) \ xss \} \\
\max \cdot \text{map sum} \cdot \text{foldr ini} [[]] &= \{ \text{fold fusion, zplus } x \ xss = 0 : \text{map} \ (x+) \ xss \} \\
\max \cdot \text{foldr zplus} [0] &= \{ \text{fold fusion, let } z_{\max} \ x \ y = 0 \uplus (x + y) \} \\
\text{foldr} \ z_{\max} 0.
\end{align*}
\]

The fold fusion works because \( \uplus \) distributes into \((+)\):

\[
\begin{align*}
\max \ (0 : \text{map} \ (x+) \ xs) &= 0 \uplus \max \ (\text{map} \ (x+) \ xs) \\
&= 0 \uplus (x + \max \ xs).
\end{align*}
\]

Back to Maximum Segment Sum

We reason:

\[
\begin{align*}
\max \cdot \text{map sum} \cdot \text{concat} \cdot \text{map inits} \cdot \text{tails} &= \{ \text{since map } f \cdot \text{concat} = \text{concat} \cdot \text{map} \ (\text{map } f) \} \\
\max \cdot \text{concat} \cdot \text{map} \ (\text{map sum}) \cdot \text{map inits} \cdot \text{tails} &= \{ \text{since max } \cdot \text{concat} = \max \cdot \text{map max} \} \\
\max \cdot \text{map max} \cdot \text{map} \ (\text{map sum}) \cdot \text{map inits} \cdot \text{tails} &= \{ \text{since map } f \cdot \text{map } g = \text{map} \ (f \cdot g) \} \\
\max \cdot \text{map} \ (\text{foldr} \ z_{\max} 0) \cdot \text{tails} &= \{ \text{reasoning in the previous slides} \} \\
\max \cdot \text{foldr} \ z_{\max} 0. \\
\end{align*}
\]

max \cdot scanr 0.
Maximum Segment Sum in Linear Time!

- We have derived \( mss = \text{max} \cdot \text{scanr} \ zmax 0 \), where \( zmax x y = 0 \uparrow (x + y) \).
- The algorithm runs in linear time, but takes linear space.
- A tupling transformation eliminates the need for linear space.

\[
mss = \text{fst} \cdot \text{maxhd} \cdot \text{scanr} \ zmax 0
\]

where \( \text{maxhd} xs = (\text{max} xs, \text{hd} xs) \). We omit this last step in the lecture.
- The final program is \( mss = \text{fst} \cdot \text{foldr} \ \text{step} \ (0, 0) \), where \( \text{step} x \ (m, y) = ((0 \uparrow (x + y)) \uparrow m, 0 \uparrow (x + y)) \).

4.4 Folds on Trees

Folds on Trees

- Folds are not limited to lists. In fact, every datatype with so-called “regular base functors” induces a fold.
- Recall some datatypes for trees:

\[
\begin{align*}
\text{data } iTree \alpha &= \text{Null} | \text{Node } a \ (iTree \alpha) \ (iTree \alpha); \\
\text{data } eTree \alpha &= \text{Tip } a | \text{Bin } (eTree \alpha) \ (eTree \alpha).
\end{align*}
\]

- The fold for \( iTree \), for example, is defined by:

\[
\begin{align*}
\text{foldiT } f \ e \ \text{Null} &= e, \\
\text{foldiT } f \ e \ (\text{Node } a \ t \ u) &= f \ a \ (\text{foldiT } f \ e \ t) \ (\text{foldiT } f \ e \ u).
\end{align*}
\]

- The fold for \( eTree \), is given by:

\[
\begin{align*}
\text{foldeT } f \ g \ (\text{Tip } x) &= g \ x, \\
\text{foldeT } f \ g \ (\text{Bin } t \ u) &= f \ (\text{foldeT } f \ g \ t) \ (\text{foldeT } f \ g \ u).
\end{align*}
\]

Some Simple Functions on Trees

- to compute the size of an \( iTree \):

\[
\text{sizeiTree} = \text{foldiT} \ (\lambda x \ m \ n.m + n + 1) 0.
\]

- To sum up labels in an \( eTree \):

\[
\text{sumeTree} = \text{folddT} \ (+) \ \text{id}.
\]

- To compute a list of all labels in an \( iTree \) and an \( eTree \):

\[
\begin{align*}
\text{flatteniT} &= \text{foldiT} \ (\lambda x \ xs \ ys.xs ++ [x] ++ ys) [], \\
\text{flatteneT} &= \text{folddT} \ (+) \ (\lambda x.x[]).
\end{align*}
\]
5 Unfolds

Unfolds Generate Data Structures

- While folds consumes a data structure, unfolds builds data structures.
- Unfold on lists is defined by:

  \[ \text{unfoldr } p f s = \begin{cases} [ ] & \text{if } p s \\ \text{let } (x, s') = f s \text{ in } x : \text{unfoldr } p f s' \end{cases}. \]

The value \( s \) is a “seed” to generate a list with. Function \( p \) checks the seed to determine whether to stop. If not, function \( f \) is used to generate an element and the next seed.

5.1 Unfold on Lists

Some Useful Functions Defined as Unfolds

- For brevity let us introduce the “split” notation. Given functions \( f :: \alpha \to \beta \) and \( g :: \alpha \to \gamma \), \( \langle f, g \rangle :: \alpha \to (\beta, \gamma) \) is a function defined by:

  \[ \langle f, g \rangle a = (f a, g a). \]

- The function call \( \text{fromto } m n \) builds a list \( [n, n+1, \ldots, m] \):

  \[ \text{fromto } m = \text{unfoldr } (\geq m) \langle \text{id}, (1+) \rangle. \]

- The function \( \text{tails}^+ \) is like \( \text{tails} \), but returns non-empty tails only:

  \[ \text{tails}^+ = \text{unfoldr } \text{null} \langle \text{id}, \text{tl} \rangle, \]

  where \( \text{null } xs \) yields \text{true} iff \( xs = [ ] \).

Unfolds May Build Infinite Data Structures

- The function call \( \text{from } n \) builds the infinitely long list \( [n, n+1, \ldots] \):

  \[ \text{from } = \text{unfoldr } \text{const } \text{false} \langle \text{id}, (1+) \rangle. \]

- More generally, \( \text{iterate } f x \) builds an infinitely long list \( [x, f x, f (f x) \ldots] \):

  \[ \text{iterate } f = \text{unfoldr } \text{const } \text{false} \langle \text{id}, f \rangle. \]

  We have \( \text{from } = \text{iterate } (1+) \).

Merging as an Unfold

- Given two sorted lists \( (xs, ys) \), the call \( \text{merge } (xs, ys) \) merges them into one sorted list:

  \[
  \begin{align*}
  \text{merge} & = \text{unfoldr } \text{null2 } \text{mrg} \\
  \text{null2 } (xs, ys) & = \text{null } xs \land \text{null } ys \\
  \text{mrg } ([], y : ys) & = (y, ([], ys)) \\
  \text{mrg } (x : xs, []) & = (x, (xs, [])) \\
  \text{mrg } (x : xs, y : ys) & = \begin{cases} (x, (xs, y : ys)) & \text{if } x \leq y \\ (y, (x : xs, ys)) & \text{else} \end{cases}. 
  \end{align*}
\]
5.2 Folds v.s. Unfolds

Folds and Unfolds

- Folds and unfolds are dual concepts. Folds consume data structure, while unfolds build data structures.
- List constructors have types: \((:) \colon \alpha \rightarrow [\alpha] \rightarrow [\alpha] \) and \([\_] : [\alpha] ; \) in \(\text{fold } f \ e\), the arguments have types: \(f : \alpha \rightarrow \beta \rightarrow \beta\) and \(e : \beta\).
- List deconstructors have types: \(\langle \text{hd, tl} \rangle : [\alpha] \rightarrow (\alpha, [\alpha])\); in \(\text{unfoldr } p \ f\), the argument \(f\) has type \(\beta \rightarrow (\alpha, \beta)\).
- They do not look exactly symmetrical yet. But that is just because our notations are not general enough.

Folds v.s. Unfolds

- Folds are defined on inductive datatypes. All inductive datatypes are finite, and emit inductive proofs. Folds basically captures induction on the input.
- As we have seen, unfolds may generate infinite data structures.
  - They are related to coinductive datatypes.
  - Proof by induction does not (trivially) work for coinductive data in general. We need to instead use coinductive proof.

A Sketch of A Coinductive Proof

To prove that \(\text{map } f \cdot \text{iterate } f = \text{iterate } f (f \ x)\), we show that for all possible observations, the lhs equals the rhs.

- \(\text{hd} \cdot \text{map } f \cdot \text{iterate } f = \text{hd} \cdot \text{iterate } f (f \ x)\). Trivial.
- \(\text{tl} \cdot \text{map } f \cdot \text{iterate } f = \text{tl} \cdot \text{iterate } f (f \ x)\):

\[
\begin{align*}
\text{tl} \ (\text{map } f \ (\text{iterate } f \ x)) \\
= \ & \text{tl} \ (f \ x : \text{map } f \ (\text{iterate } f \ (f \ x))) \\
= & \ \{\text{hypothesis}\} \\
= \ & \text{tl} \ (f \ x : \text{iterate } f \ (f \ x))) \\
= & \ \text{tl} \ (\text{iterate } f \ (f \ x)).
\end{align*}
\]

The hypothesis looks a bit shaky: isn’t it circular reasoning? We need to describe it in a more rigorous setting to establish its validity. This is out of the scope of this lecture.

Unfolds on Trees

Unfolds can also be extended to trees. For internally labelled binary trees we define:

\[
\text{unfoldiT } p \ f \ s \ = \ \begin{cases}
\text{if } p \ s \text{ then Null} & \text{else} \\
\text{let } (x, s_1, s_2) = f \ s & \\
\text{in } \text{Node } x (\text{unfoldiT } p \ f \ s_1) & (\text{unfoldiT } p \ f \ s_2).
\end{cases}
\]

And for externally labelled binary trees we define:

\[
\text{unfoldeT } p \ f \ g \ s \ = \ \begin{cases}
\text{if } p \ s \text{ then Tip } (g \ s) & \text{else} \\
\text{let } (s_1, s_2) = f \ s & \\
\text{in } \text{Bin } (\text{unfoldeT } p \ f \ g \ s_1) & (\text{unfoldeT } p \ f \ g \ s_2).
\end{cases}
\]
6 Hylomorphism

Unflattening a Tree

- Recall the function $\text{flatteneT} :: e\text{Tree}\,\alpha \rightarrow [\alpha]$, defined as a fold, flattening a tree into a list. Let us consider doing the reverse.
- Assume that we have the following functions:
  - $\text{single}\,xs = \text{true}$ iff $xs$ contains only one element.
  - $\text{half} :: [\alpha] \rightarrow ([\alpha],[\alpha])$ split a list of length $n$ into two lists of lengths roughly half of $n$.
- The function $\text{unflatteneT}$ builds a tree out of a list:
  \[
  \begin{align*}
  \text{unflatteneT} & :: [\alpha] \rightarrow e\text{Tree}\,[\alpha], \\
  \text{unflatteneT} & = \text{unfoldeT}\,\text{single}\,\text{half}\,\text{id}.
  \end{align*}
  \]

6.1 A Museum of Sorting Algorithms

Mergesort as a Hylomorphism

- Recall the function $\text{merge}$ merging a pair of sorted lists into one sorted list. Assume that it has a curried variant $\text{merge}_c$.
- What does this function do?
  \[
  \text{msort} = \text{foldeT}\,\text{merge}_c\,\text{id} \cdot \text{unflatteneT}
  \]
- This is mergesort!

Quicksort as a Hylomorphism

- Let $\text{partition}$ be defined by:
  \[
  \text{partition}(x:xs) = (x,\text{filter}\,\leq\,x\,xs,\text{filter}\,>\,x\,xs).
  \]
- Recall the function $\text{flatteniT}$ flattening an $i\text{Tree}$, defined by a fold.
- Quicksort can be defined by:
  \[
  \text{qsort} = \text{flatteniT} \cdot \text{unfoldiT}\,\text{null}\,\text{partition}.
  \]
- Compare and notice some symmetry:
  \[
  \begin{align*}
  \text{qsort} & = \text{flatteniT} \cdot \text{partitioniT}, \\
  \text{msort} & = \text{mergeeT} \cdot \text{unflatteneT}.
  \end{align*}
  \]
  Both are defined as a fold after an unfold.
Insertion Sort and Selection Sort

- Insertion sort can be defined by an fold:
  \[
  isort = \text{foldr } \text{insert } [],
  \]
  where \text{insert} is specified by
  \[
  \text{insert } x \, xs = \text{takeWhile } (\prec x) \, xs ++ [x] ++ \text{dropWhile } (\prec x) \, xs.
  \]

- Selection sort, on the other hand, can be naturally seen as an unfold:
  \[
  ssort = \text{unfoldr } \text{null } \text{select},
  \]
  where \text{select} is specified by
  \[
  \text{select } xs = (\text{max } xs, xs - [\text{max } xs]).
  \]

6.2 Hylomorphism and Recursion

Hylomorphism

- A fold after an unfold is called a hylomorphism.
- The unfold phase expands a data structure, while the fold phase reduces it.
- The divide-and-conquer pattern, for example, can be modelled by hylomorphism on trees.
- To avoid generating an intermediate tree, the fold and the unfold can be fused into a recursive function. E.g. let \( hyoI_f e p g = \text{foldIT } f e \cdot \text{unfoldIT } p g \), we have
  \[
  hyoiT f e p g s = \begin{cases}
  e & \text{if } p \, s \\
  \text{let } (x, s_1, s_2) = g \, s \\
  \text{in } f \, x \, (hyoI_f e p g s_1) & \text{else} \\
  \end{cases}
  \]

Hylomorphism and Recursion

Okay, we can express hylomorphisms using recursion. But let us look at it the other way round.

- Imagine a programming in which you are not allowed to write explicit recursion. You are given only folds and unfolds for algebraic datatypes\(^1\).
- When you do need recursion, define a datatype capturing the pattern of recursion, and split the recursion into a fold and an unfold.
- This way, we can express any recursion by hylomorphisms!

Therefore, the hylomorphism is a concept as expressive as recursive functions (and, therefore, the Turing machine) — if we are allowed to have hylomorphisms, that is.

\(^1\)Built from regular base functors, if that makes any sense.
Folds Take Inductive Types

- So far, we have assumed that it is allowed to write \( \text{fold} \cdot \text{unfold} \). However, let us not forget that they are defined on different types!

- Folds take inductive types.
  - If we use folds only, everything terminates (a good property!).
  - Recall that we assume a simple model of functions between sets.
  - On the downside, of course, not every program can be written in terms of folds.

Unfolds Return Coinductive Types

Unfolds returns coinductive types.

- We can generate infinite data structure.

- But if we are allowed to use only unfolds, every program still terminates because there is no “consumer” to infinitely process the infinite data.

- Not every program can be written in terms of unfolds, either.

Hylomorphism, Recursion and Termination

If we allow \( \text{fold} \cdot \text{unfold} \),

- we can now express every program computable by a Turing machine.

- But, we need a model assuming that inductive types and coinductive types coincide.

- Therefore, folds must prepare to accept infinite data.

- Therefore, some programs may fail to terminate!

- Which means that partial functions have emerged.

- Recursive equations may not have unique solutions.

- And everything we believe so far are not on a solid basis anymore!

Termination, Type Theory, Semantics . . .

- One possible way out: instead of total function between sets, we move to partial functions between complete partial orders, and model what recursion means in this setting.

- There are also alternative approaches staying with functions and sets, but talk about when an equation has a unique solution.

- This is where all the following concepts and fields meet each other: unique solutions, termination, type theory, semantics, programming language theory, computability theory . . . and a lot more!
7 Wrapping Up

What have we learned?

- To derive programs from specification, functional programming languages allows the expand/reduce transformation.
- A number of properties we need can be proved by induction.
- To capture recurring patterns in reasoning, we move to structural recursion: folds captures induction, while unfolds capture coinduction.
  - We gave lots of examples of the fold-fusion rule.
  - Unfolds are equally important, unfortunately we ran out of space.
- Hylomorphism is as expressive as you can get. However, it introduces non-termination. And that opens rooms for plenty of related research.

Where to Go from Here?

- The Functional Pearls column in Journal of Functional Programming has lots of neat example of derivations.
- Procedural program derivation (basing on the weakest precondition calculus) is another important branch we did not talk about.
- There are plenty of literature about folds, and
- more recently, papers about unfolds and coinduction.
- You may be interested in theories about inductive types, coinductive types, and datatypes in general,
- and semantics, denotational and operational,
- which may eventually lead you to category theory!

Part III

Procedural Program Derivation

From Day 1 and Day 2...

We have covered a lot about functional program derivation:

- Expand/reduce transformation, and proof by induction.
- Some derivation techniques: accumulating parameter, tupling.
- Folds and fold fusion.
- Unfolds and hylomorphism.

For something you can apply to your work in the “real world”, we will talk about deriving procedural programs in the last part of this lecture.

Most of the materials are taken from Anne Kaldewaij’s book Programming: the Derivation of Algorithms.
8 The Guarded Command Language

The Guarded Command Language

- A program computing the greatest common divisor:

\[
\begin{align*}
&\text{\(\text{con} A, B : \text{int}; \{\text{0} < A \land \text{0} < B\}\)} \\
&\text{\(\var x, y : \text{int};\)} \\
&\text{\(x, y := A, B;\)} \\
&\text{\(\text{do} \ y < x \rightarrow x := x - y\)} \\
&\text{\(\quad [ x < y \rightarrow y := y - x\)} \\
&\text{\(\text{od}\)} \\
&\text{\{x = y = gcd(A, B)\}} \\
\end{align*}
\]

- Notice: a section for declarations, followed by a section for statements.
- Assignments: :=; \textbf{do} denotes loops with guarded bodies.
- Assertions delimited in curly brackets.

Assertions

- The \textit{state} space of a program is the states of all its variables.
  - E.g. the GCD program has state space \(Z \times Z\).
- The \textit{Hoare triple} \(\{P\}S\{Q\}\), operationally, denotes that the statement \(S\), when executed in a state satisfying \(P\), \textit{terminates} in a state satisfying \(Q\).
  - E.g., \(\{P\}S\{\text{true}\}\) expresses that \(S\) terminates.
  - \(\{P\}S\{Q\}\) and \(P_0 \Rightarrow P\) implies \(\{P_0\}S\{Q\}\).
  - \(\{P\}S\{Q\}\) and \(Q \Rightarrow Q_0\) implies \(\{P\}S\{Q_0\}\).
- Perhaps the simplest statement: \(\{P\}\text{skip}\{Q\}\) iff. \(P \Rightarrow Q\).

Verification vs. Derivation

- Recall the relationship between verification and derivation:
  - Verification: given a program, prove that it is correct with respect to some specification.
  - Derivation: start from the specification, and attempt to construct only correct programs.
- For this course, verification is mostly about putting in the right assertions.
- We will talk about verification first, before moving on to derivation.
8.1 Assignments and Selection

Substitution and Assignments

- $P[E/x]$: substituting occurrences of $x$ in $P$ for $E$.
  - E.g. $(x \leq 3)[x - 1/x] \equiv x - 1 \leq 3 \equiv x \leq 4$.

- Which is correct:
  1. $\{P\}x := E\{P[E/x]\}$, or
  2. $\{P[E/x]\}x := E\{P\}$?

- Answer: 2! For example:

\[
\{ (x \leq 3)[x + 1/x] \}x := x + 1\{x \leq 3 \} \\
\equiv \{ x + 1 \leq 3 \}x := x + 1\{x \leq 3 \} \\
\equiv \{ x \leq 2 \}x := x + 1\{x \leq 3 \}.
\]

E.g. Swapping Booleans

- The $\equiv$ operator is defined by
  \[
  \begin{align*}
  \text{true} \equiv \text{true} &= \text{true} \\
  \text{false} \equiv \text{true} &= \text{false} \\
  \text{true} \equiv \text{false} &= \text{false} \\
  \text{false} \equiv \text{false} &= \text{true}
  \end{align*}
  \]

- $(a \equiv b) \equiv c = a \equiv (b \equiv c); \text{true} \equiv a = a$.

- Verify:

\[
|\var a, b : \text{bool}; \\
\{ a \equiv A \land b \equiv B \} \Rightarrow \{ b \equiv B \land a \equiv b \equiv A \} \\
\text{a} := \text{a} \equiv \text{b}; \\
\{ b \equiv B \land \text{a} \equiv b \equiv A \} \Rightarrow \{ \text{a} \equiv a \equiv b \equiv B \land \text{a} \equiv b \equiv A \} \\
\text{b} := \text{a} \equiv \text{b}; \\
\{ \text{a} \equiv \text{b} \equiv B \land \text{b} \equiv A \} \\
\text{a} := \text{a} \equiv \text{b}; \\
\{ \text{a} \equiv \text{B} \land \text{b} \equiv A \}
|
\]

Selection

- Selection takes the form if $B_0 \rightarrow S_0[\ldots[B_n \rightarrow S_n].fi$.

- Each $B_i$ is called a guard; $B_i \rightarrow S_i$ is a guarded command.

- If none of the guards $B_0, \ldots, B_n$ evaluate to true, the program aborts. Otherwise, one of the command with a true
  guard is chosen non-deterministically and executed.

- To annotate an if statement:

\[
\{P\} \\
\text{if} B_0 \rightarrow \{P \land B_0\} S_0\{Q\} \\
\| B_1 \rightarrow \{P \land B_1\} S_1\{Q\} \\
\text{fi} \\
\{Q, Pf\},
\]

where $Pf :: P \Rightarrow B_0 \lor B_1$. 
Binary Maximum

- Goal: to assign \( z = x \uparrow y \) to \( z \). By definition, 
  \[ z = x \uparrow y \equiv (z = x \lor z = y) \land x \leq z \land y \leq z. \]

- Try \( z := x \). We reason:
  \[
  (z = x \lor z = y) \land x \leq z \land y \leq z
  \]
  \[
  \equiv (x = x \lor x = y) \land x \leq x \land y \leq x
  \]
  \[
  \equiv y \leq x,
  \]
which hinted at using a guarded command: \( y \leq x \rightarrow z := x \).

- Indeed:
  \[
  \begin{align*}
  \{true\} & \rightarrow \{y \leq x\} z := x \{z = x \uparrow y\} \\
  & \lor \{x \leq y\} z := y \{z = x \uparrow y\} \\
  \textbf{fi}
  & \{z = x \uparrow y\}.
  \end{align*}
  \]

8.2 Repetition

Loops

- Repetition takes the form \( \textbf{do} B_0 \rightarrow S_0 \rightarrow \ldots \rightarrow B_n \rightarrow S_n \textbf{od} \).

- If none of the guards \( B_0 \ldots B_n \) evaluate to true, the loop terminates. Otherwise one of the commands is chosen non-deterministically, before the next iteration.

- To annotate a loop (for partial correctness):
  \[
  \begin{align*}
  \{P\} & \rightarrow \{P \land B_0\} S_0\{P\} \\
  & \lor \{P \land B_1\} S_1\{P\} \\
  \textbf{od}
  & \{Q, Pf\},
  \end{align*}
  \]
  where \( Pf :: P \land \neg B_0 \land \neg B_1 \Rightarrow Q \).

- \( P \) is called the loop invariant. Every loop should be constructed with an invariant in mind!

Linear-Time Exponentiation

\[
\begin{align*}
\llbracket \textbf{con} & N\{0 \leq N\}; \textbf{var} x, n : \text{int} ; \\
x, n := 1, 0 ; \\
\{x = 2^n \land n \leq N\} \\
\textbf{do} n \neq N \rightarrow \\
\{x = 2^n \land n \leq N \land n \neq N\} \\
x, n := x + x, n + 1 \\
\{x = 2^n \land n \leq N, Pf1\} \\
\textbf{od} \\
\{x = 2^N, Pf2\} \\
\rrbracket
\]
Pf1:
\[
(x = 2^n \land n \leq N)[x + x, n + 1/x, n]
\equiv x + x = 2^{n+1} \land n + 1 \leq N
\equiv x = 2^n \land n < N
\]
Pf2:
\[
x = 2^n \land n \leq N \land (n \neq N)
\Rightarrow x = 2^N
\]

Greatest Common Divisor
- Known: $gcd(x, x) = x$; $gcd(x, y) = gcd(x, x - y)$ if $x > y$.
  \[
  \begin{align*}
  &|\text{con } A, B : \text{int}; \{0 < A \land 0 < B\} \\
  &\text{var } x, y : \text{int}; \\
  &x, y := A, B; \{0 < x \land 0 < y \land gcd(x, y) = gcd(A, B)\} \\
  &\text{do } y < x \rightarrow x := x - y \\
  &\quad \{x < y \rightarrow y := y - x\} \\
  &\text{od} \{x = gcd(A, B) \land y = gcd(A, B)\}
  \end{align*}
\]
  \[
  (0 < x \land 0 < y \land gcd(x, y) = gcd(A, B))[x - y/x]
  \equiv 0 < x - y \land 0 < y \land gcd(x - y, y) = gcd(A, B)
  \Leftarrow 0 < x \land 0 < y \land gcd(x, y) = gcd(A, B) \land y < x
  \]

A Weird Equilibrium
- Consider the following program:
  \[
  \begin{align*}
  &|\text{var } x, y, z : \text{int}; \\
  &\{\text{true, bnd = } 3 \times (x \uparrow y \uparrow z) - (x + y + z)\} \\
  &\text{do } x < y \rightarrow x := x + 1 \\
  &\quad y < z \rightarrow y := y + 1 \\
  &\quad z < x \rightarrow z := z + 1 \\
  &\text{od} \{x = y = z\}
  \end{align*}
  \]
  \[
  \begin{align*}
  &\text{If it terminates at all, we do have } x = y = z. \text{ But why does it terminate?} \\
  &1. \ bnd \geq 0, \text{ and } bnd = 0 \text{ implies none of the guards are true.} \\
  &2. \ {x < y \land bnd = t} x := x + 1\{bnd < t\}.
  \end{align*}
  \]

Repetition
- To annotate a loop for total correctness:
  \[
  \begin{align*}
  &\{P, bnd = t\} \\
  &\text{do } B_0 \rightarrow \{P \land B_0\} S_0\{P\} \\
  &\quad B_1 \rightarrow \{P \land B_1\} S_1\{P\} \\
  &\text{od} \{Q\}
  \end{align*}
  \]
  we have got a list of things to prove:
1. \( B \land \neg B_0 \land \neg B_1 \Rightarrow Q, \)
2. for all \( i \), \( \{ P \land B_i \} S_i \{ P \} \),
3. \( P \land (B_1 \lor B_2) \Rightarrow t \geq 0, \)
4. for all \( i \), \( \{ P \land B_i \land t = C \} S_i \{ t < C \} \).

E.g. Linear-Time Exponentiation
- What is the bound function?
  \[
  \begin{align*}
  \text{let } & x, n := 1, 0; \\
  & \{ x = 2^n \land n \leq N, N - n \} \\
  & \text{do } n \neq N \rightarrow \\
  & \quad x, n := x + x, n + 1 \\
  & \text{od} \\
  & \{ x = 2^N \}
  \end{align*}
  \]
- \( x = 2^n \land n \neq N \Rightarrow N - n \geq 0, \)
- \( \{ \ldots \land N - n = t \} x, n := x + x, n - 1 \{ N - n < t \} \).

E.g. Greatest Common Divisor
- What is the bound function?
  \[
  \begin{align*}
  \text{let } & x, y := A, B; \\
  & \{ 0 < x \land 0 < y \land gcd(x, y) = gcd(A, B), bnd = |x - y| \} \\
  & \text{do } y < x \rightarrow x := x - y \\
  & \quad \{ x < y \rightarrow y := y - x \\
  & \quad \text{od} \\
  & \{ x = gcd(A, B) \land y = gcd(A, B) \}
  \end{align*}
  \]
- \( \ldots \Rightarrow |x - y| \geq 0, \)
- \( \{ \ldots 0 < y \land y < x \land |x - y| = t \} x := x - y \{ |x - y| < t \} \).

9 Procedural Program Derivation

Deriving Programs from Specifications
- From such a specification:
  \[
  \begin{align*}
  \text{let } & \text{declarations; } \\
  & \{ \text{preconditions} \} \\
  & \text{prog} \\
  & \{ \text{postcondition} \}
  \end{align*}
  \]
we hope to derive \( \textit{prog} \).

• We usually work backwards from the post condition.

• The techniques we are about to learn is mostly about constructing loops and loop invariants.

9.1 Taking Conjuncts as Invariants

Conjunctive Postconditions

• When the post condition has the form \( P \land Q \), one may take one of the conjuncts as the invariant and the other as the guard:

\[
\{ P \} \textbf{do } \neg Q \rightarrow S \textbf{ od } \{ P \land Q \}.
\]

• E.g. consider the specification:

\[
\begin{align*}
| \textbf{con } A, B : \text{int}; \{ 0 \leq A \land 0 \leq B \} \\
\textbf{var } q, r : \text{int}; \\
\textbf{divmod } \\
\{ q = A \div B \land r = A \mod B \} \\
|.
\end{align*}
\]

• The post condition expands to \( R : A = q \times B + r \land 0 \leq r \land r < B \).

Computing the Quotient and the Remainder

Let try \( A = q \times B + r \land 0 \leq r \) as the invariant and \( \neg (r < B) \).

\[
q, r := 0, A;
\{ P :: A = q \times B + r \land 0 \leq r \} \\
\textbf{do } B \leq r \rightarrow \\
\quad q := q + 1; \\
\quad r := r - B \\
\textbf{ od } \\
\{ P \land r < B \}
\]

• \( P \) is established by \( q, r := 0, A \).

• Choose \( r \) as the bound.

• Since \( B > 0 \), try \( r := r - B \):

\[
\begin{align*}
\text{\( P[r - B/r] \)}} & \equiv A = q \times B + r - B \land 0 \leq r - B \\
& \equiv A = (q - 1) \times B + r \land B \leq r.
\end{align*}
\]

\[
(A = (q - 1)B + r \land B \leq r)[q + 1/q] \]

\[
\Leftarrow A = q \times B + r \land B \leq r
\]
9.2 Replacing Constants by Variables

Quantifications

- Given associative \(+\) with identity \(e\), we denote \(x m \oplus x (m + 1) \cdots \oplus x (n - 1)\) by \((\oplus i : m \leq i < n : x i)\).
- \((\oplus i : n \leq i < n : x i) = e\).
- \((\oplus i : m \leq i < n + 1 : x i) = (\oplus i : m \leq i < n : x i) \oplus x n\) if \(m \leq n\).
- E.g.
  - \(- (i : 3 \leq i < 5 : i^2) = 3^2 + 4^2 = 25\).
  - \(- (i, j : 3 \leq i \leq j < 5 : i \times j) = 3 \times 3 + 3 \times 4 + 4 \times 4\).
  - \(- (\land i : 2 \leq i < 9 : \text{odd } i \Rightarrow \text{prime } i) = \text{true}\).
  - \(- (i \cdot j : 1 \leq i < 7 : -i^2 + 5j) = 6\) (when \(i = 2\) or \(3\)).
- As a convention, \(+ i : 0 \leq i < n : x i\) is written \((\Sigma i : 0 \leq i < n : x i)\).

Summing Up an Array

\[
\begin{align*}
|| \text{con } N : \text{int}; \{0 \leq N\} f : \text{array} [0..N] \text{of} \text{int}; \\
n, x := 0, 0; \\
\{x = (\Sigma i : 0 \leq i < n : f i) \land 0 \leq n, \text{bnd} : N - n\} & \quad \text{do} \ n \neq N \rightarrow x := x + f n; \ n := n + 1 \od \\
\{x = (\Sigma i : 0 \leq i < n : f i)\} & \quad ||
\end{align*}
\]

- Inv. is established by \(n, x := 0, 0\).

- Use \(N - n\) as bound, try incrementing \(n\):
  
  \[
  (x = (\Sigma i : 0 \leq i < n : f i) \land 0 \leq n)[n + 1/n] \\
  \equiv x = (\Sigma i : 0 \leq i < n + 1 : f i) \land 0 \leq n + 1 \\
  \leq x = (\Sigma i : 0 \leq i < n + 1 : f i) \land 0 \leq n \\
  \equiv x = (\Sigma i : 0 \leq i < n : f i) + f n \land 0 \leq n
  \]

\[
(x = (\Sigma i : 0 \leq i < n : f i) + f n) \land 0 \leq n)[x + f n/x] \\
\equiv x + f n = (\Sigma i : 0 \leq i < n : f i) + f n \land 0 \leq n \\
\leq x = (\Sigma i : 0 \leq i < n : f i) \land 0 \leq n
\]

9.3 Strengthening the Invariant

Fibonacci

Recall: \(\text{fib} 0 = 0, \text{fib} 1 = 1,\) and \(\text{fib} (n + 2) = \text{fib} n + \text{fib} (n + 1)\).

\[
|| \text{con } N : \text{int}; \{0 \leq N\} \ \text{var} \ x, y : \text{int}; \\
n, x, y := 0, 0, 1; \\
\{x = \text{fib} n \land 0 \leq n \leq N \land y = \text{fib} (n + 1)\} & \quad \text{do} \ n \neq N \rightarrow x, y := y, x + y; \ n := n + 1 \od \\
\{x = \text{fib} N\} ||
\]

- Inv. is established by \(n, x := 0, 0\).
• \((x = \text{fib } n \land 0 \leq n \leq N \land y = \text{fib } (n+1)) [n+1/n] \equiv x = \text{fib } (n+1) \land 0 \leq n < N \land y = \text{fib } (n+2)\)

\((x = \text{fib } (n+1) \land \ldots \land y = \text{fib } (n+2)) [y/x, y/y]\)

\(\equiv y = \text{fib } (n+1) \land \ldots \land x + y = \text{fib } (n+2)\)

\(\Leftarrow x = \text{fib } n \land \ldots \land y = \text{fib } (n+1)\)

9.4 Tail Invariants

Using Associativity

• Consider again computing \(A^B\). Notice that:

\[x^0 = 1,\]

\[x^y = 1 \times (x \times x)^{y \div 2} \quad \text{if even } y,\]

\[= x \times x^{y-1} \quad \text{if odd } y.\]

• Starting from \(A^B\), we can use the properties above to keep “shifting some value to the left” until we have \(x_1 \times \ldots \times 1\).

• Also notice that we need \(\times\) to be associative.

Using Associativity

• In general, to achieve \(r = f X\) where

\[f x = a \quad \text{if } b x,\]

\[f x = g x \oplus f (h x) \quad \text{if } \neg b x.\]

for associative \(\oplus\) with identity \(e\), we may:

\[x, r := X, e;\]

\{ \(r \oplus f x = f X\}\}

\[\text{do } \neg b x \rightarrow x, r := h x, r \oplus g x \text{ od};\]

\{ \(r \oplus a = f X\}\}

\[r := r \oplus a.\]

• Verify:

\( (r \oplus f x = f X)[h x, r \oplus g x/x, r] \equiv (r \oplus g x) \oplus f (h x) = f X \equiv r \oplus (g x \oplus f (h x)) = f X \equiv r \oplus f x = f X.\)

Fast Exponentiation

• To achieve \(r = A^B\), choose invariant \(r \times x^y = A^B\):

\[r, x, y := 1, A, B;\]

\{ \(r \times x^y = A^B \land 0 \leq y, \text{bnd} = y\}\}

\[\text{do } y \neq 0 \land \text{even } y \rightarrow x, y := x \times x, y \div 2\]

\[\quad \lnot y \neq 0 \land \text{odd } y \rightarrow r, y := r \times x, y - 1\]

\[\text{od}\]

\{ \(r \times x^y = A^B \land y = 0\}\).
• Verify the second branch, for example:

\[
(r \times x^y = A^B)[r \times x, y - 1/r, y] \\
\equiv (r \times x) \times x^{y-1} = A^B \\
\equiv r \times (x \times x^{y-1}) = A^B \\
\Leftarrow r \times x^y = A^B \land y < 0.
\]

10 Maximum Segment Sum, Procedually

Specification

\[
\begin{array}{l}
|\{\textbf{con } N : \text{int}; \{0 \leq N\} f : \text{array}[0..N] \text{of int}; \}
\begin{array}{l}
\textbf{var } r, n : \text{int};
\end{array} \\
\begin{array}{l}
n, r := 0, 0;
\end{array} \\
\begin{array}{l}
\{\{ r = (\uparrow p, q : 0 \leq p \leq q \leq n : \text{sum } p \ q) \land 0 \leq n \leq N \} \\
\textbf{do } n \neq N \rightarrow \\
\end{array} \\
\begin{array}{l}
\text{\ldots; } n := n + 1
\end{array} \\
\textbf{od} \\
\begin{array}{l}
\{ r = (\uparrow p, q : 0 \leq p \leq q \leq N : \text{sum } p \ q) \}
\end{array}
\end{array}
\]

• \( \text{sum } p \ q = \sum_{i : p \leq i < q} f \ i. \)

• Replacing constant \( N \) by variable \( n \), use an up-loop.

Strengthening the Invariant

• Let \( P_0 \equiv r = (\uparrow p, q : 0 \leq p \leq q \leq n : \text{sum } p \ q). \)

\[
\begin{array}{l}
n, r, s := 0, 0, 0; \\
\{ P_0 \land 0 \leq n \leq N \land s = (\uparrow p : 0 \leq p \leq n : \text{sum } p \ n) \} \\
\textbf{do } n \neq N \rightarrow \\
\text{\ldots; } n := n + 1 \\
\textbf{od} \\
\begin{array}{l}
\{ r = (\uparrow p, q : 0 \leq p \leq q \leq N : \text{sum } p \ q) \}
\end{array}
\end{array}
\]

\[
\begin{array}{l}
(r = (\uparrow p, q : 0 \leq p \leq q \leq n : \text{sum } p \ q) \land 0 \leq n \leq N)[n + 1/n] \\
\equiv (r = (\uparrow p, q : 0 \leq p \leq q \leq n + 1 : \text{sum } p \ q) \land 0 \leq n + 1 \leq N \\
\equiv (r = (\uparrow p, q : 0 \leq p \leq q \leq n : \text{sum } p \ q) \uparrow \\
(\uparrow p, q : 0 \leq p \leq n + 1 : \text{sum } p(n + 1)) \\
\land 0 \leq n + 1 \leq N
\end{array}
\]

• Let’s introduce \( P_1 \equiv s = (\uparrow p : 0 \leq p \leq n : \text{sum } p \ n). \)

Constructing the Loop Body

• Known: \( P_0 \equiv r = (\uparrow p, q : 0 \leq p \leq q \leq n : \text{sum } p \ q). \)

• \( P_1 \equiv s = (\uparrow p : 0 \leq p \leq n : \text{sum } p \ n). \)

• \( P_0[n + 1/n] \equiv r = (\uparrow p, q : 0 \leq p \leq q \leq n : \text{sum } p \ q) \uparrow (\uparrow p : 0 \leq p \leq n + 1 : \text{sum } p(n + 1)). \)
Therefore, a possible strategy would be:

\[
\{ P_0 \land P_1 \ldots \}
\]
\[
s := ?;
\]
\[
\{ P_0 \land P_1[n + 1/n] \ldots \}
\]
\[
r := r \uparrow s;
\]
\[
\{ P_0[n + 1/n] \land P_1[n + 1/n] \ldots \}
\]
\[
n := n + 1
\]
\[
\{ P_0 \land P_1 \ldots \}
\]

**Updating the Prefix Sum**

Recall \( P_1 \equiv s = ( \uparrow p : 0 \leq p \leq n : \text{sum } p n ) \).

\[
( \uparrow p : 0 \leq p \leq n : \text{sum } p n )[n + 1/n]
\]
\[
= \uparrow p : 0 \leq p \leq n + 1 : \text{sum } p (n+1)
\]
\[
= (\uparrow p : 0 \leq p \leq n : \text{sum } p (n+1)) \uparrow \text{sum } (n+1)(n+1)
\]
\[
= (\uparrow p : 0 \leq p \leq n : \text{sum } p (n+1)) \uparrow 0
\]
\[
= (\uparrow p : 0 \leq p \leq n : (\text{sum } p n + f n)) \uparrow 0
\]
\[
= ((\uparrow p : 0 \leq p \leq n : \text{sum } p n ) + f n) \uparrow 0
\]

Thus, \( \{ P_1 \} s := ?\{ P_1[n + 1/n] \} \) is satisfied by \( s := (s + f n) \uparrow 0 \).

**Derived Program**

```plaintext
| [\textbf{con} N : \textit{int}; \{ 0 \leq N \} \ f : \textbf{array}[0..N) \textbf{of} \ \textit{int};

\textbf{var} r, s, n : \textit{int};

n, r, s := 0, 0, 0;
\{ P_0 \land P_1 \land 0 \leq n \leq N, bnd : N - n \}
\textbf{do} n \neq N \rightarrow
\hspace{1em} s := (s + f n) \uparrow 0;
\hspace{1em} r := r \uparrow s;
\hspace{1em} n := n + 1
\textbf{od}
\{ r = (\uparrow 0 \leq p \leq q \leq N : s : \text{um } p q) \}
```

- \( P_0 \equiv r = (\uparrow 0 \leq p \leq q \leq n : s : \text{um } p q) \).
- \( P_1 \equiv s = (\uparrow 0 \leq p \leq n : s : \text{um } p n) \).

## 11 Wrapping Up

### What have we learned?

- Procedural program derivation by backwards reasoning.

- Key to procedural program derivation: every loop shall be built with an invariant and a bound in mind.

- Some techniques to construct loop invariants:
  - taking conjuncts as invariants;
  - replacing constants by variables;
– strengthening the invariant;
– tail invariants.

• Some of them are closely related to techniques we introduced in Day 1 and Day 2, e.g. tupling and accumulating parameters.

What’s Missing?

• Side-effects strictly forbidden in expressions.
• That means aliasing could cause disasters,
• which in turn makes call-by-reference dangerous.
  – Extra care must be taken when we introduce subroutines.
• And, no pointers. Which means that we have problem talking about complex data structures.
  – In contrast, functional program derivation is essentially built on a theory of data structure.
  – Rescue: separation logic, to talk about when data structure is shared.

Where to Go from Here?

• Early issues of Science of Computer Programming have regular columns for program derivation.
• Books and papers by Dijkstra, Gries, Back, Backhouse, etc.
• You might not actually derive programs, but knowledge learnt here can be applied to program verification.
  – Plenty of tools around for program verification basing on pre/post-conditions. Some of them will be taught in the next summer school.
• You might never derive any more programs for the rest of your life. But the next time you need a loop, you will know better how to construct it and why it works.

References

The following list of references is certainly not complete, but may serve as a starting point if you are interested in related topics.
